Before the fixes

The course starter accepted invalid input in all three functions.

Starter application

A numeric plate series was accepted, a negative trip total was returned, and a one-axle vehicle was classified as a truck.

```
> python highway_toll.py
Inputs in order: KA-05-12-1234, -1x150, 1

==== Running parse_plate ====
Enter a plate (e.g. KA-05-AB-1234): State, District and Number: ('KA', 5, 1234)

==== Running trip_cost ====
Enter trips x rate (e.g. 3x150): Trip Cost: -150

==== Running axle_class ====
Enter an axle count (e.g. 3): Vehicle Class: truck
```

Hypothesis tests against the starter

Three invalid-input properties failed. Shrunk cases included a numeric plate series, -1x150 for trip cost, and False for the axle count.

```
> python -m pytest -p no:cacheprovider -v --tb=no --color=no test_highway_toll.py
======================================== test session starts ========================================
platform win32 -- Python 3.12.14, pytest-9.2.0, pluggy-1.7.0 -- python.exe

```

After the fixes

The application reports validation errors and continues to the next prompt.

Fixed application

The same three inputs now produce a validation message for each field.

```
> python highway_toll.py
Inputs in order: KA-05-12-1234, -1x150, 1

==== Running parse_plate ====
Enter a plate (e.g. KA-05-AB-1234): Invalid input: expected a plate like KA-05-AB-1234.

==== Running trip_cost ====
Enter trips x rate (e.g. 3x150): Invalid input: expected nonnegative whole numbers in the form 3x150.

==== Running axle_class ====
Enter an axle count (e.g. 3): Invalid input: expected a whole axle count of at least 2.
```

Hypothesis tests against the fixed application

All six properties passed. Each function was tested with valid and invalid inputs.
The command panels show captured output from the actual runs.

```
> python -m pytest -p no:cacheprovider -v --tb=no --color=no test_highway_toll.py
